Bitcoin against its long-run trend

Price near **79,000**. The **valuation fit** models price against how long the network has existed, on a log-log scale. Fair value near **135,000**, about **42% below the line**. Fitted floor near **59,000**.

A valuation anchor, not a timing tool.

It is a statistical fit of price to time. It has no hard economic mechanism behind it, cannot call tops, and may fail outside the historical sample.

Bitcoin has closed above that floor for roughly 95% of the historical sample. That is an in-sample observation, not a tested probability and not a guaranteed level of support.

Distant reference points. Never targets. Never a reason to size up.

42% and 43% is one fact, not two.

Our **cycle gauge** reports the second number. It fits the same shape of curve, price against network age, on a different price history and with a different band, then adds halving timing to classify the phase.

Because it is the same kind of fit run over overlapping data, **close agreement is close to guaranteed**. It tells you nothing the first number did not.

Do not read the two figures as confirming each other.

Six turbulent. The rest calm.

TURBULENT · 6

**bitcoin · ether · gold · silver · platinum ·
USDCHF**

CALM · THE REST

**solana · six of seven FX pairs · S&P 500 ·
oil · copper · natural gas**

The average market is contained, even though a few names carry wide ranges.

Big crypto is carrying double its normal range.

Bitcoin, 1-week vol	54% vs 39 median
----------------------------	------------------

Ether, 1-week vol	102% vs 53 median
--------------------------	-------------------

Both read turbulent at seven days while their thirty-day classifications stay calm. The horizons disagree, which flags a near-term disturbance without telling us whether it lasts.

**Direction is a coin flip.
We publish that.**

49%

over 320 backtested crypto direction calls.

Volatility clusters and can be forecast: 66% correct at seven days and 73% at thirty days in a five-year point-in-time backtest, 11 and 17 points above baseline. Direction does not. We forecast the first and say so about the second.

Next week we score this issue in public.

The model calls **bitcoin, ether, gold, silver, platinum and USDCHF turbulent**, and the rest calm.

In the next Signal we score every one of those calls the way the model does, whether realised volatility came in above or below the asset's running median, and show the hits and the misses.
